HW 1-2: ROCK-PAPER-SCISSORS

In a game of rock-paper-scissors (RPS), each player chooses to play Rock (R), Paper (P), or Scissors (S). The rules are: R beats S; S beats P; and P beats R. We will encode a rock-paper-scissors game as a list, where the elements are themselves 2-element lists that encode a player's name and a player's selected move, as shown below:

```
[ [ "Armando", "P" ], [ "Dave", "S" ] ] # Dave would win since S > P
```

Part A: Write a method `rps_game_winner` that takes a two-element list and behaves as follows:

- If the number of players is not equal to 2, raise `WrongNumberOfPlayersError`.
- If either player's strategy is something other than "R", "P" or "S" (case-insensitive), raise `NoSuchStrategyError`.
- Otherwise, return the name and move of the winning player. If both players play the same move, the first player is the winner.

We'll get you started:

```
class WrongNumberOfPlayersError < StandardError ; end
class NoSuchStrategyError < StandardError ; end

def rps_game_winner(game)
  raise WrongNumberOfPlayersError unless game.length == 2
  # your code here
end
```

Part B: We will define a rock-paper-scissors tournament to be an array of games in which each player always plays the same move. A rock-paper-scissors *tournament* is encoded as a bracketed array of games:

```
[
  [
    [ [ "Armando", "P" ], [ "Dave", "S" ] ],
    [ [ "Richard", "R" ], [ "Michael", "S" ] ],
  ],
  [
    [ [ "Allen", "S" ], [ "Omer", "P" ] ],
    [ [ "David E.", "R" ], [ "Richard X.", "P" ] ]
  ]
]
```

In the tournament above, Armando will always play P and Dave will always play S. This tournament plays out as follows:

In the tournament above Armando will always play P and Dave will always play S. This tournament plays out as follows:

- Dave would beat Armando ($S > P$),
- Richard would beat Michael ($R > S$), and then
- Dave and Richard would play (Richard wins since $R > S$).

Similarly,

- Allen would beat Omer,
- Richard X would beat David E., and
- Allen and Richard X. would play (Allen wins since $S > P$).

Finally,

- Richard would beat Allen since $R > S$.

Note that the tournament continues until there is only a single winner.

Tournaments can be nested arbitrarily deep, i.e., it may require multiple rounds to get to a single winner. You can assume that the initial tournament is well-formed (that is, there are 2^n players, and each one participates in exactly one match per round).

Write a method `rps_tournament_winner` that takes a tournament encoded as a bracketed array and returns the winner (for the above example, it should return `["Richard", "R"]`).

[Choose Files](#) No file chosen

```
On Time
#rps_game_winner
should be defined
should raise WrongNumberOfPlayersError if there are not exactly two players [1 point]
should raise NoSuchStrategyError if there is some strategy that is not R, P, or S [4 points]
should return the correct winner in a simple RPS game with a clear winner [15 points]
should return the first player in the case of a tie [10 points]

#rps_tournament_winner
should be defined
should still be able to handle the case where a tournament is just one game [10 points]
should pass the example given in the homework of an 8-player tournament [5 points]
should pass a basic test case of 8 players [15 points]
should return the correct winner in the cases of 16 and 32-man tournaments [40 points]

Finished in 0.01844 seconds
10 examples, 0 failures
```
